Introduction

Problem Statement

We address the problem of a target **aircraft** that tries to evade an **attacker** missile and avoid being hit by it.

Thesis Overview

This thesis deals with the following problems:

TA: Target-Attacker

- 2-agent pursuit-evasion
- Target (aircraft) and attacker (missile)
- Seeking optimal escape maneuver

TAD: Target-Attacker-Defender

- 3-agent pursuit-evasion
- Target (aircraft), defender (missile), and attacker (missile)
- Seeking safe region, and optimal heading angles

Unity Game

An experimental game to find the best escape maneuver of a TA problem by collecting and analyzing data from human players.

Target-Attacker

Summary of Solution

Scenario 1:

TA: Target-Attacker

- We present several methodologies to find the **optimal escape maneuver** for a target against an attacking missile.
- We simulate 2D proportional-navigation using MATLAB and Simulink.
- Optimization is achieved via the techniques of Monte-Carlo simulation and genetic algorithms.

Main References

Zarchan, Paul (2012)

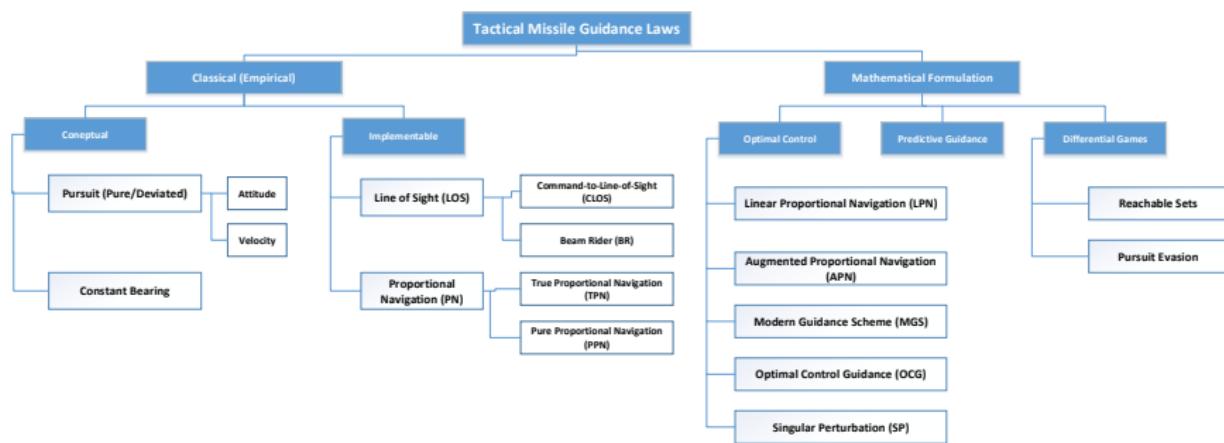

Tactical and strategic missile guidance

American Institute of Aeronautics and Astronautics.

Target-Attacker Assumptions

- The missile is on the ground at (0,0). The plane is in the air at (10000,40000).
- The missile is faster than the aircraft, but cannot turn tighter than the aircraft, so it takes a longer path.
- The control mechanism of the Missile is much simpler and is of less capability than that of the aircraft. In order to pull as tight turn as the aircraft, it must exercise an acceleration that is far beyond its capability.
- Missile always attempts to trace the target. Thus if the target changes heading, it will necessary for the Missile to change heading similarly, but this is too difficult for him to achieve.
- The main problem with evading missiles is their speed, which makes timing somewhat difficult.

Guidance Laws

Proportional Navigation

The proportional navigation guidance law issues acceleration commands, perpendicular to the instantaneous missile-target line-of-sight, which are proportional to the line-of-sight rate and closing velocity. Mathematically, the guidance law can be stated as

$$n_c = N' V_c \dot{\lambda}$$

where n_c is the acceleration command (for the missile) in (m/s^2), N' is the effective navigation ratio, a unit-less designer-chosen gain (usually in the range of $3 \rightarrow 5$), V_c is the missile-target closing velocity in (m/s) and $\dot{\lambda} = \frac{d\lambda}{dt}$ is the rate of the line-of-sight angle and is in (rad/s).

Proportional Navigation Equations - Geometry

$$V_{T1} = -V_T \cos(\beta)$$

$$V_{T2} = V_T \sin(\beta)$$

$$R_{TM1} = RT1 - RM1$$

$$R_{TM2} = RT2 - RM2$$

$$R_{TM} = \sqrt{R_{TM1}^2 + R_{TM2}^2}$$

$$\lambda = \tan^{-1}\left(\frac{R_{TM2}}{R_{TM1}}\right)$$

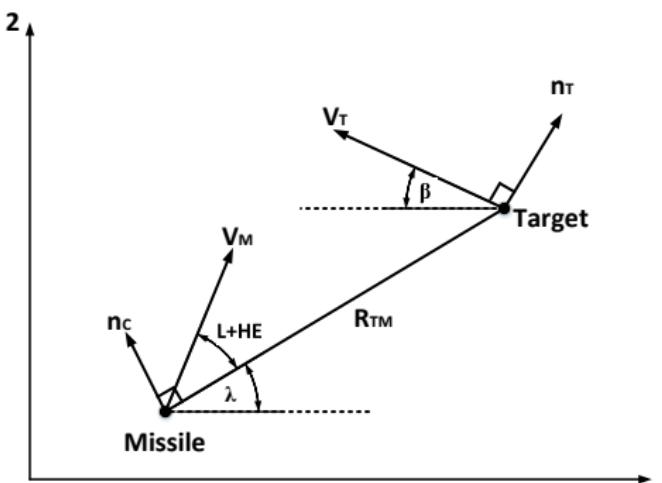

$$L = \sin^{-1}\left(\frac{V_T \sin(\beta + \lambda)}{V_M}\right)$$

$$V_{M1} = V_M \cos(\theta + HE)$$

$$V_{M2} = V_M \sin(\theta + HE)$$

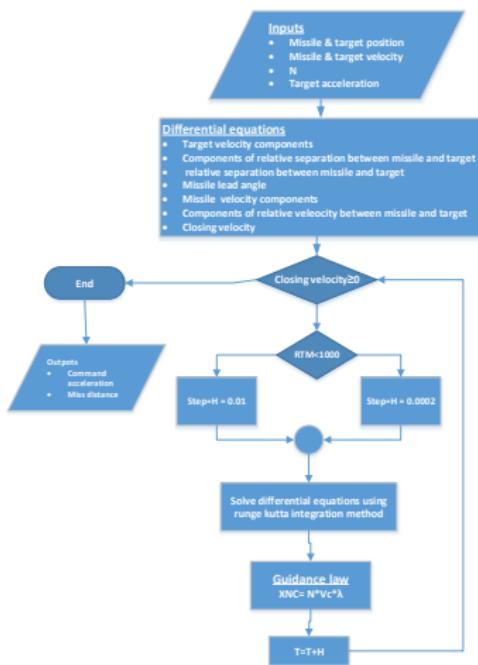

$$V_{TM1} = V_{T1} - V_{M1}$$

$$V_{TM2} = V_{T2} - V_{M2}$$

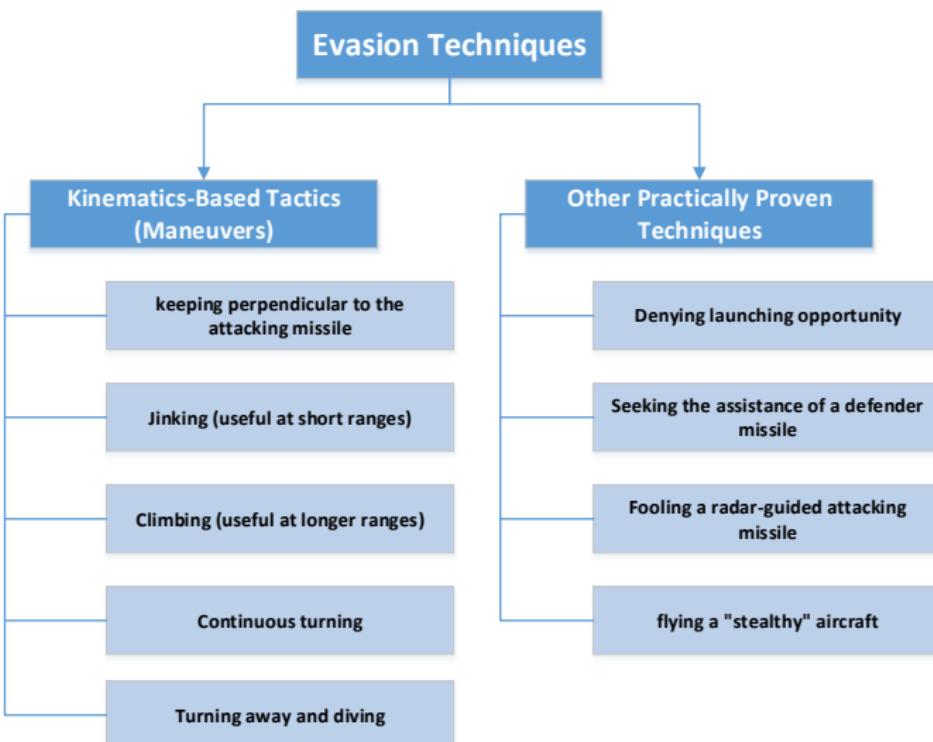

2d geometry of TA engagement.

Proportional Navigation Flowchart

Evasion Tactics Taxonomy

Evasion Tactics

1. keeping perpendicular to the attacking missile:

- Turn hard to either left or right so as to fly at roughly 90 degrees angle to attacking aircraft (This forces missile to bleed off the energy and to lead the target).
- Once target aircraft makes a hard turn to reverse a direction, missile with its far larger turn circle will be unable to compensate.

Evasion Tactics

2. Jinking (useful at short ranges):

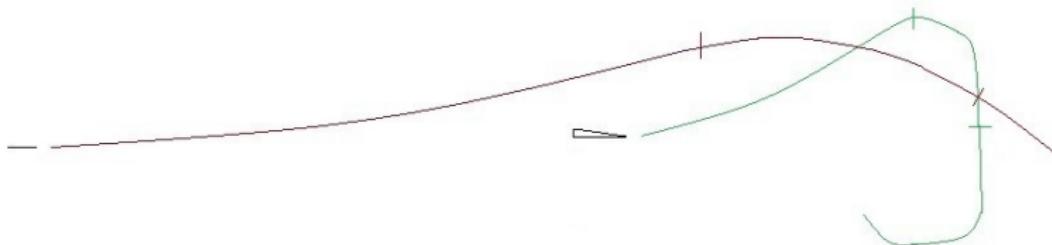

- Aircraft must be positioned so that it is at angle (30-60 degrees is optimum) relative to missiles flight path.
- Once missile gets closer, aircraft will make a hard turn in opposite direction.
- As there is a lag between aircraft changing the direction and missile following (for several reasons, most important of which is missiles inertia), this will cause missile to head in wrong direction until it manages to correct, and also to bleed off the energy.
- Missile will fly past the aircraft and miss.

Evasion Tactics

3. Climbing (useful at longer ranges):

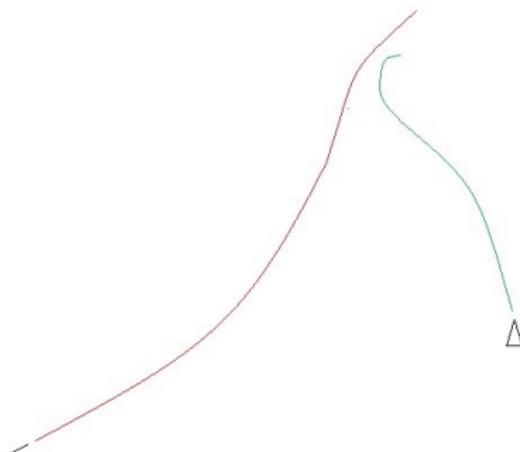

- Since at long range missile will have burned out its engine, it will rely on inertia to keep it flying, and climbing will mean that it will bleed off energy rapidly.
- Once missile reaches a close range (maybe around 1,500 meters), dive for the ground, then pull up (This will allow pilot to gain energy and using it to evade the missile).

Evasion Tactics

4. Continuous turning:

- place the missile at 3 o'clock or 9 o'clock position
- maintain sufficient turn to keep the missile
- This tactic forces the missile to execute a continuous turn, bleeding the energy entire time, making it easier to outturn the missile once it comes close.

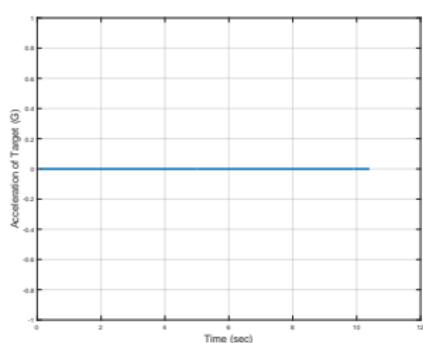

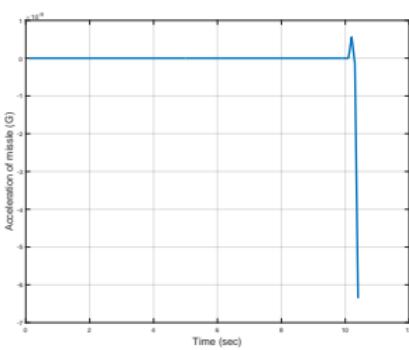

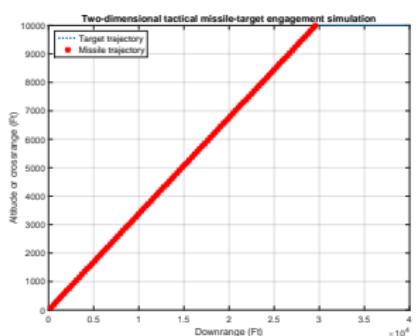

Target Maneuver Cases

- Zero Target maneuver
- Constant Target maneuver
- Polynomial Target maneuver
- Trapezoidal Target maneuver

Target Maneuver Cases

Zero Target maneuver. Heading error = 0 and $N' = 4$.

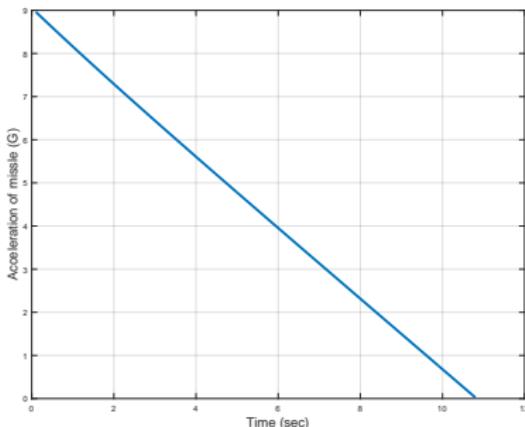

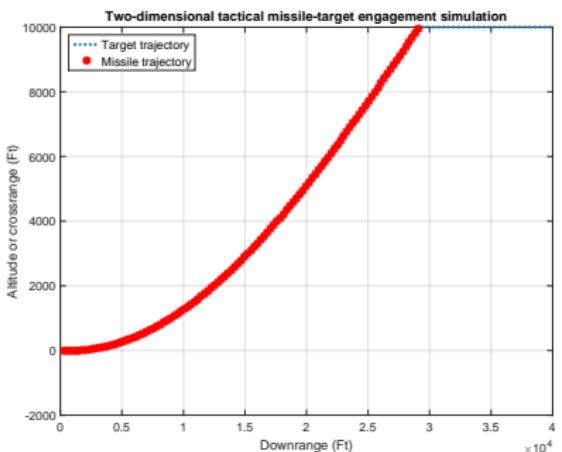

Target and attacker trajectories.

Attacker (missile) acceleration.

Target acceleration.

Target Maneuver Cases

Zero Target maneuver. Heading error = -20 and $N' = 3$.

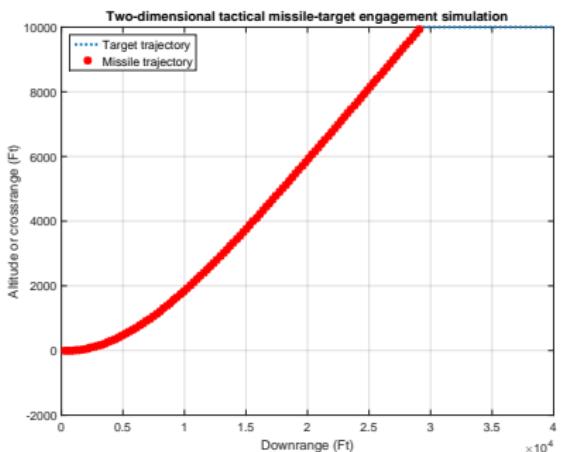

Target and attacker
trajectories.

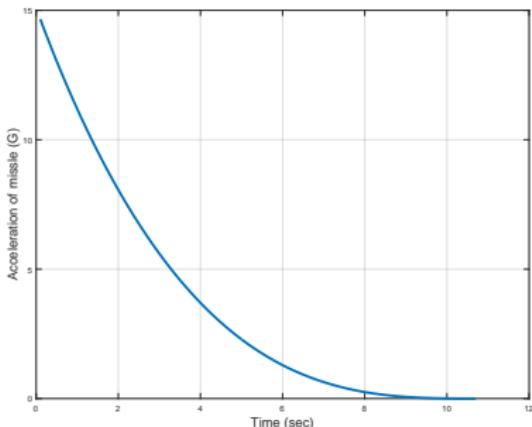

Attacker (missile)
acceleration.

Target Maneuver Cases

Zero Target maneuver. Heading error = -20 and $N' = 5$.

Target and attacker trajectories.

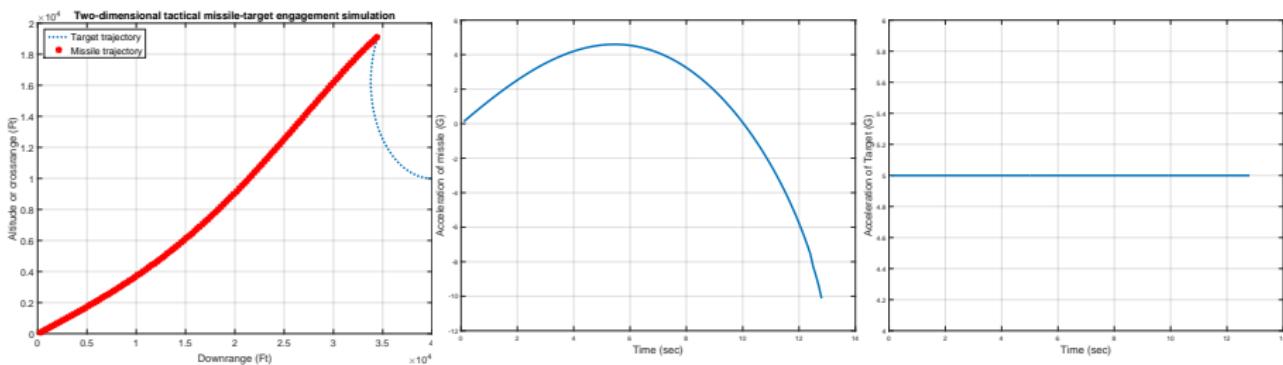

Attacker (missile) acceleration.

- Increasing the effective navigation ratio causes heading error to be removed rapidly.
- The effective navigation ratio has an effect on the acceleration of the missile; the way that the missile will bleed energy.
- The total acceleration (area under the curve) is increasing inversely proportional with the effective navigation ratio N' .

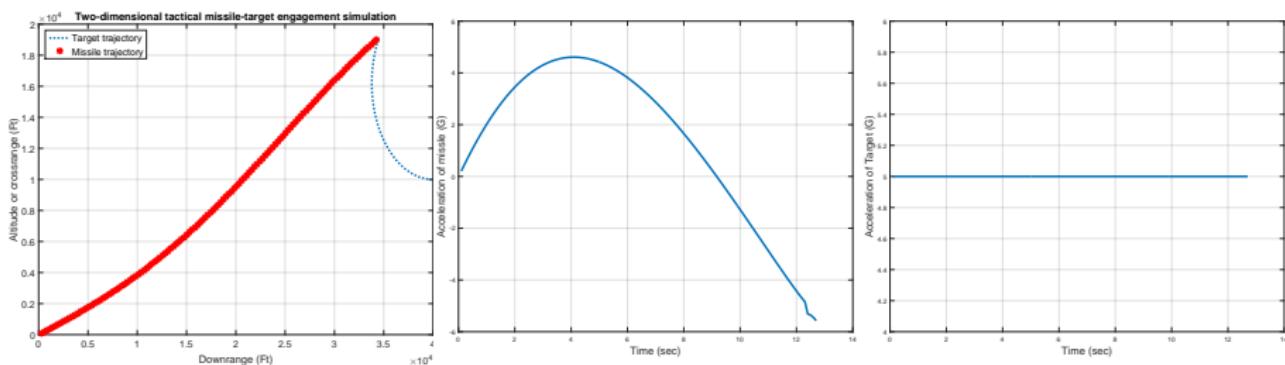

Target Maneuver Cases

Constant Target maneuver ($XNT = 5G$, $HE = 0$, $N' = 3$)

Target Maneuver Cases

Constant Target maneuver ($XNT = 5G$, $HE = 0$, $N' = 5$)

- Higher effective navigation ratio yields less acceleration to hit maneuvering target.
- This causes the missile to lead the target slightly more than a lower effective navigation ratio does.

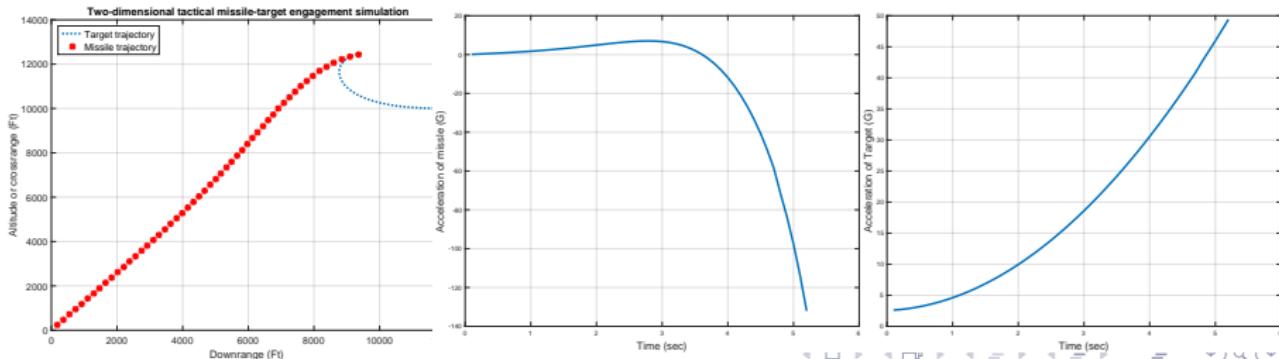

Target Maneuver Cases (Optimization)

Cost Function

- Missile acceleration
- Miss distance

Polynomial Target maneuver. (polynomial degree=3 ,
 $HE = 0$, $N' = 3$)

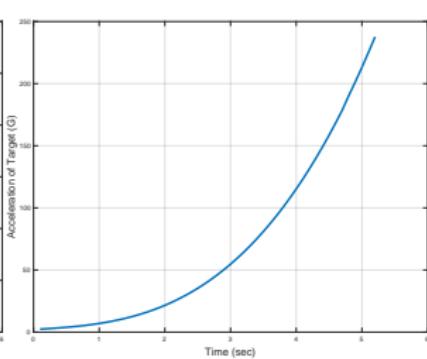

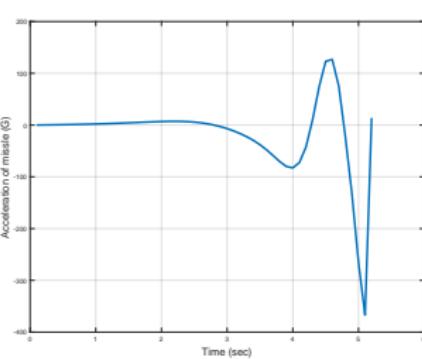

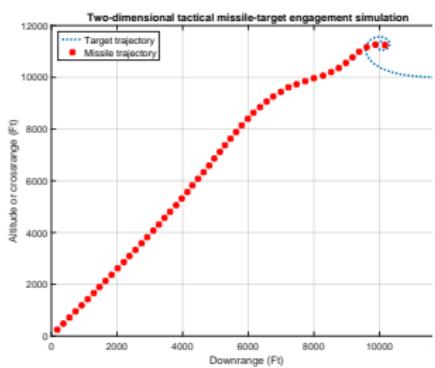

$$f(t) = c_0 + c_1 T + c_2 T^2 + c_3 T^3 + \dots + c_N T^N \quad (1)$$

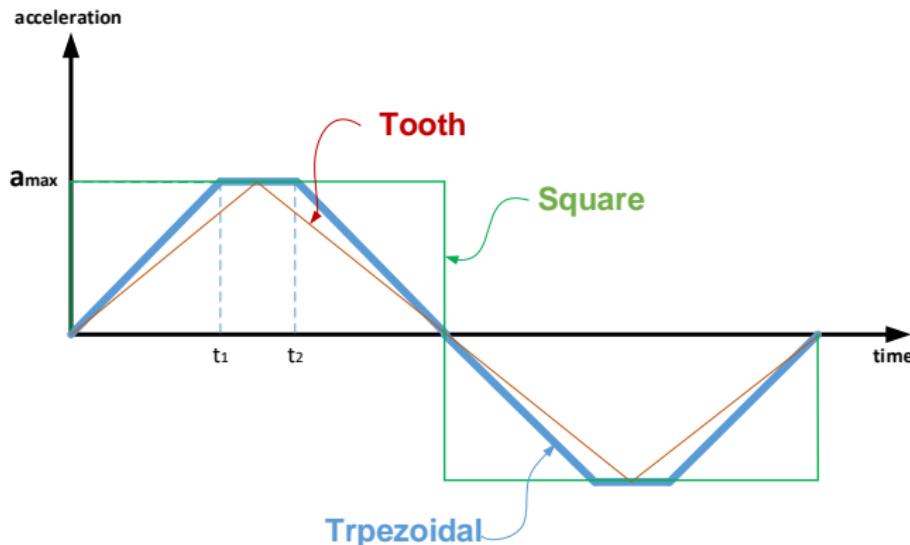

Target Maneuver Cases (Optimization)

Polynomial Target maneuver. (polynomial degree=4 ,
 $HE = 0$, $N' = 3$)

Target Maneuver Cases

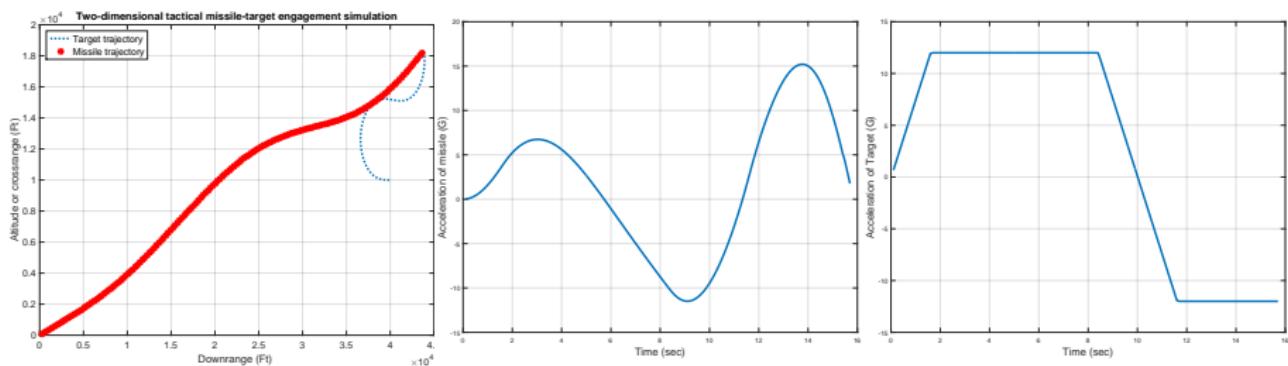

Trapezoidal Target maneuver

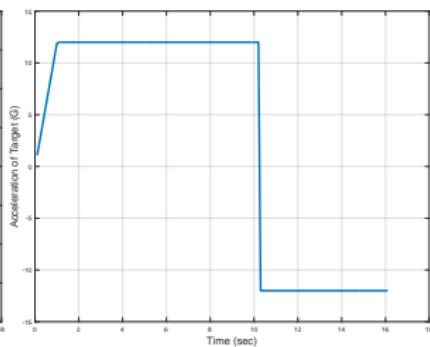

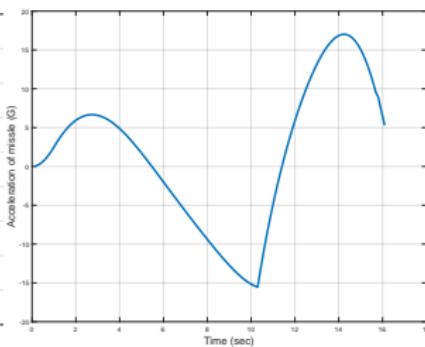

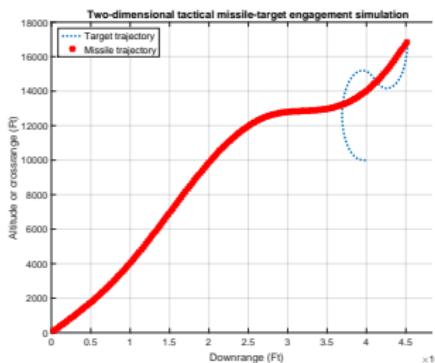

Target Maneuver Cases

Trapezoidal Target maneuver (Symmetric => Square, tooth, trapezoidal)

Target Maneuver Cases

Trapezoidal Target maneuver (not Symmetric)

Unity Game

Summary of Solution

Experimental Testing:

Unity Game

- We construct a **mathematically-correct game** of target-attacker and let many people play it taking the target side.
- We find the best escape maneuver by collecting and analyzing data of the human escape maneuver.
- The game is developed using Unity, a free readily-available cross-platform game engine.

Unity Game

Competitions between humans and computers in games of increasing difficulty, including the games of Chess , Arimaa , Jeopardy! , and Go. Typically, the rivalry is between a single human champion (such as Kasparov) against a state-of-the-art computer (such as Deep Blue) limited to a specific domain (such as Chess). The sole purpose of the competition is to decide whether the human or the computer wins more games within the same match.

Unity Game

The **gamification** phenomenon, which is the use of game design elements in non-game or learning contexts, a trend related to human-computer interactions in the form of serious games, pervasive games, alternate reality games, or playful design.

Unity Game

The paradigm of **games with a purpose**, which aims to utilize the billions of hours spent (wasted!) by contemporary humans in playing computer games. This paradigm channels game playing into useful work by directing people playing computer games to simultaneously solve large-scale problems without consciously knowing about this and, hence, without losing the element of fun or entertainment. Many large-scale open problems can be solved using collective human brainpower in this unique way. Examples include language translation, monitoring of security cameras, improving Web search, and text summarization. With the paradigm of games with a purpose, hundreds of millions of people can collaborate on the same problem via the Internet

Unity Game

Human Computation, which is the idea of using human processing power to perform tasks that computers cannot yet perform or solve problems still intractable for computers, usually in an enjoyable manner. Human Computation is also viewed as systems of computers and large numbers of humans that work together in order to solve problems that could not be solved by either computers or humans alone.

Unity Game

Crowdsourcing, which is the act of taking a job traditionally performed by a designated agent (an employee) and outsourcing it to a generally large group of people in the form of an open call. Whereas human computation replaces computers with humans, crowdsourcing replaces traditional human workers with members of the human public.

Unity Game

Unity is a cross-platform game engine developed by Unity Technologies and used to develop video games for PC, consoles, mobile devices and websites. It is a free software (<https://unity3d.com/>), working with C# programming language.

Unity Game

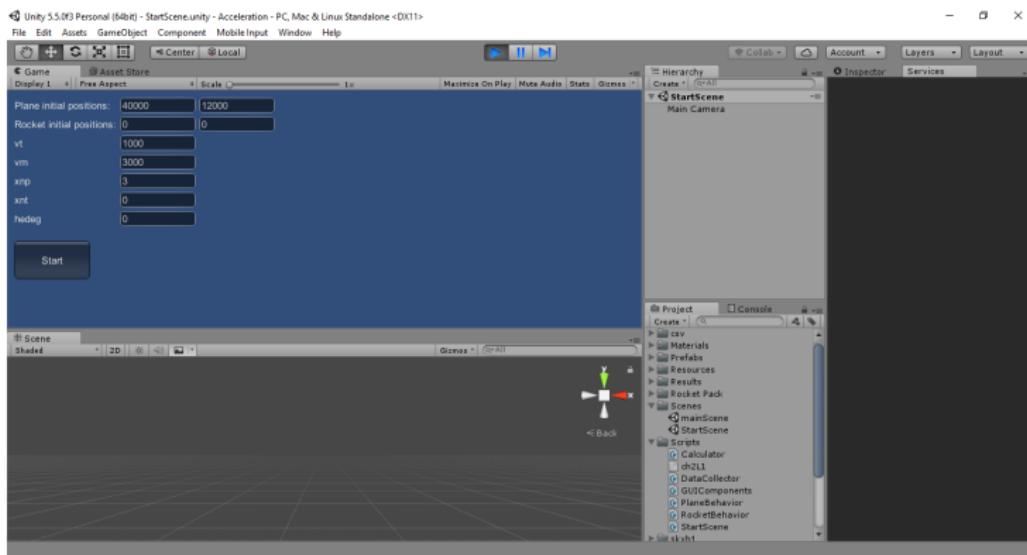

Figure: Unity game engine interface

Unity Game

Each game consists of two scenes:

1. Starting scene.
2. Game scene, which updated each frame per second.

Unity Game

In the starting scene there is data fields (position, velocity, ...). After this scene ends, all the data are destroyed, so we save the information we need in file called "player prefs".

The game scene consists of some objects, each object has his own script, this script must contain 2 points:

- Start: initialization.
- Updated : every frame.

Unity Game

The game consists of two objects: plane (Target) and missile (Attacker). A human player controls the increasing and decreasing of the target acceleration (XNT) by two arrows on the keyboard. The missile object is moving on according to the proportional navigation guidance law.

Unity Game

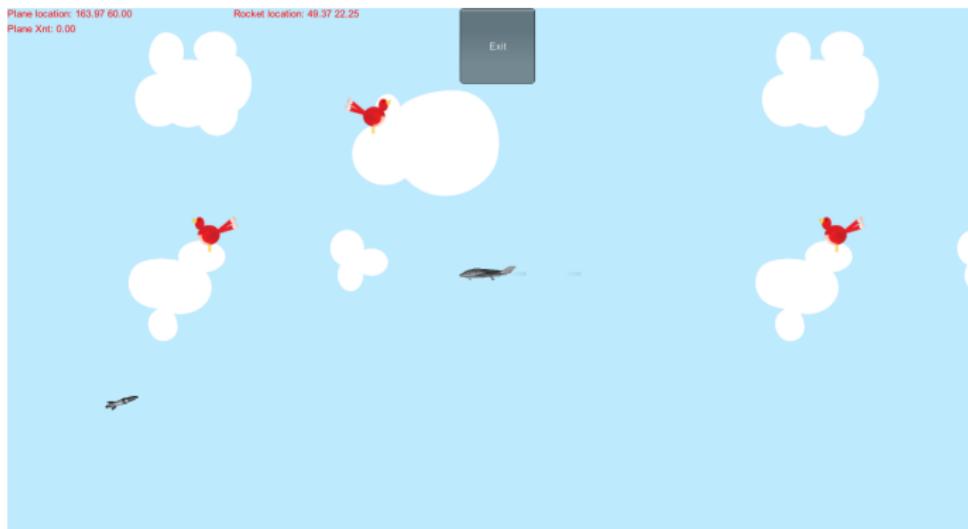

Figure: Unity game for simulating Target-Attacker engagement

Unity Game

In our game we have 3 objects:

- 1. Plane:** its script contain some commands to control the plane with two arrows in the keyboard, which increase and decrease the target acceleration by upward arrow and downward arrow respectively.
- 2. Missile:** it does not contain a script, the equations controlling its behavior is in the script with the "Data collector" object.
- 3. Object "Data collector"**

Unity Game

Object "Data collector":

- Start
 1. initialization of the variables in the equations.
 2. set the location of all objects (plane and missile).
- Update
 1. get plane location.
 2. execute your equations.
 3. update rocket location (according to PN equations).
 4. update informations to be printed to excel.
 5. check the breaking condition, if true, load starting scene.

acceleration versus
time.

Preliminary results

Our experience with Evasion-1 demonstrates that the game is working correctly. Figures 12-14 illustrate some of our preliminary results, obtained by the player with the best score so far. The target acceleration curve in Fig. 13 exhibits a Barrel-Roll behavior, an aerial maneuver in which an airplane makes a complete rotation on both its longitudinal and lateral axes, causing it to follow a helical path, approximately maintaining its original direction. This maneuver helps a target to force an attacker to fly out in front, i.e., to overshoot.

Target-Attacker-Defender

Summary of Solution

Scenario 2:

TAD: Target-Attacker-Defender

- A unified analysis is presented via the construction of two Apollonius circles, considering all possibilities of the ratio between the speeds of the attacker and defender.
- We obtain the critical target speed and the Voronoi diagram bordering the safe or escape region for the target optimal strategies. Numerical results and plots allow useful and insightful qualitative interpretations.
- Optimal heading angles to be followed by the target to stay in the safe region. We use Hamiltonian equations to formulate an exact two-point boundary value problem that is solved numerically, verifying our earlier results.

Apollonius Circles

A circle is the locus moving at a constant distance (called the circle's radius r) from a fixed point (called the circle's centre O). In the limit of an infinite radius ($r \rightarrow \infty$), the circle degenerates into a straight line.

Apollonius Circle

The locus of a point moving such that the ratio of its distances from two fixed points A and B is a constant k .

$$\frac{AI}{IB} = \frac{AE}{EB} = k, \quad \{k \neq 1\}. \quad (2)$$

The points I and E are the two special cases of P that lie on the straight line extension of the straight segment \overline{AB} . These points divide the straight segment \overline{AB} internally and externally in the ratio k ($k \neq 1$).

Express I and E in terms of \mathbf{A} and \mathbf{B} as

$$I = \frac{1}{k+1}(\mathbf{A} + k\mathbf{B}), \quad (3)$$

$$E = \frac{1}{k-1}(-\mathbf{A} + k\mathbf{B}). \quad (4)$$

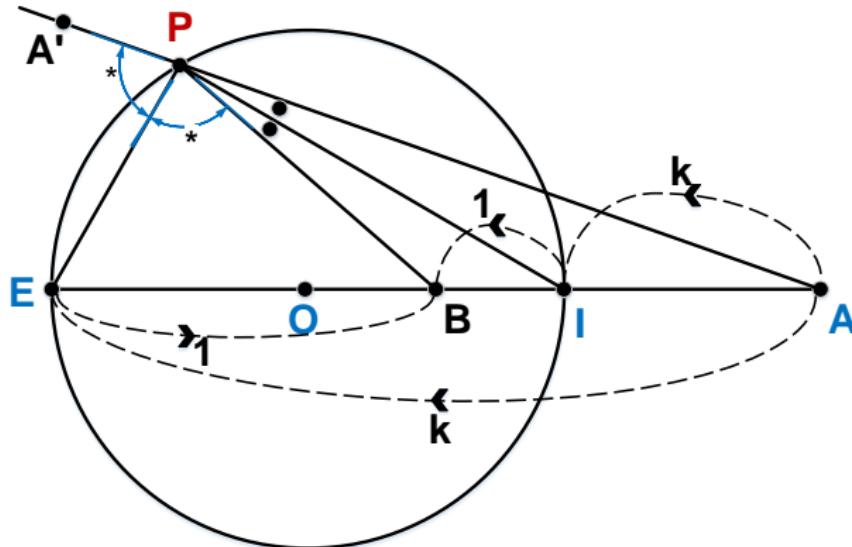

Figure: Apollonius circle for a moving point P such that $\frac{AP}{PB} = k > 1$.
Here $m\angle API = m\angle BPI$ and $m\angle A'PE = m\angle BPE$.

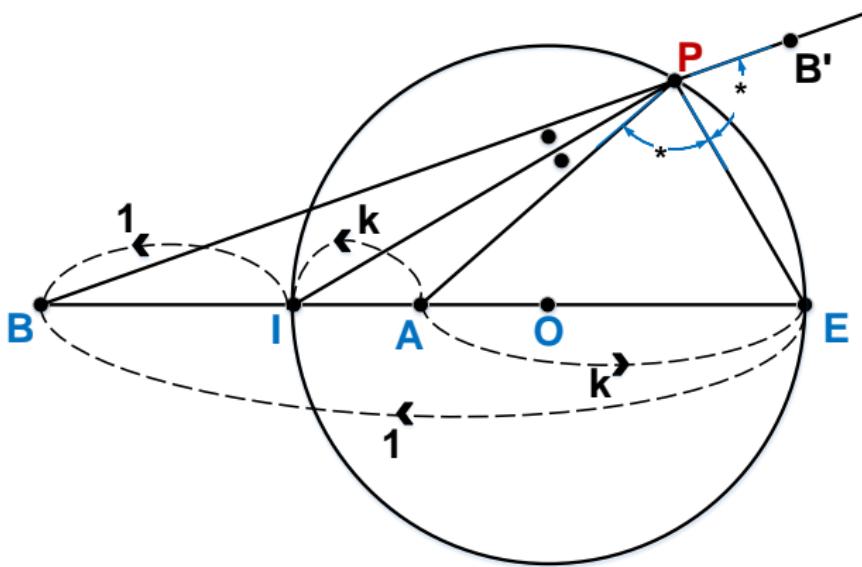

Figure: Apollonius circle for a moving point P such that $\frac{AP}{PB} = k > 1$.
 Here $m\angle API = m\angle BPI$ and $m\angle A'PE = m\angle BPE$.

Center of the Apollonius circle

center of the circle is the midpoint of points I and E

$$\begin{aligned} \mathbf{O} &= \frac{1}{2}(\mathbf{I} + \mathbf{E}) \\ &= \frac{1}{2}\left[\left(\frac{1}{k+1} - \frac{1}{k-1}\right)\mathbf{A} + k\left(\frac{1}{k+1} + \frac{1}{k-1}\right)\mathbf{B}\right] \quad (5) \\ &= -\frac{1}{k^2-1}\mathbf{A} + \frac{k^2}{k^2-1}\mathbf{B}, \end{aligned}$$

Radius of the Apollonius circle

the radius of the circle is half the length of the displacement from I to E ,

$$\begin{aligned} r &= \frac{1}{2}|I - E| \\ &= \frac{1}{2}\left|\left(\frac{1}{k+1} + \frac{1}{k-1}\right)\mathbf{A} + k\left(\frac{1}{k+1} - \frac{1}{k-1}\right)\mathbf{B}\right| \\ &= \left|\frac{k}{k^2-1}\mathbf{A} - \frac{k}{k^2-1}\mathbf{B}\right| \\ &= \left|\frac{k}{k^2-1}\right|\left|\mathbf{A} - \mathbf{B}\right| = \frac{k}{k^2-1}(AB). \end{aligned} \tag{6}$$

case of $k = 1$

It is clear from (5) and (6) that $\lim_{k \rightarrow 1} |O| \rightarrow \infty$ and $\lim_{k \rightarrow 1} r \rightarrow \infty$, and hence for $k = 1$, the Apollonius circle degenerates into a straight line, namely the perpendicular bisector of the straight segment \overline{AB} .

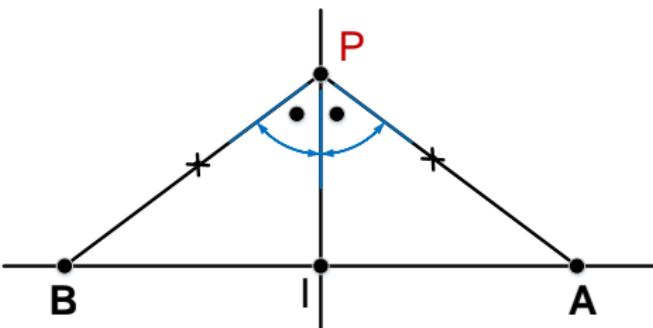

Figure: For $k = 1$, the Apollonius circle in the previous figures degenerates into the perpendicular bisector of the straight segment \overline{AB} . The point E disappears in this figure as it goes to ∞

The *AD* Apollonius circle

For the *AD* Apollonius circle, the two fixed points are the initial positions of the Attacker $\mathbf{A} = (x_A, 0)$ and the initial position of the defender $\mathbf{D} = (-x_A, 0)$. The fixed ratio of the circle k is replaced by the following dimensionless ratio:

$$\gamma = \frac{V_A}{V_D}. \quad (7)$$

Substituting the values of \mathbf{A} and \mathbf{D} above for \mathbf{A} and \mathbf{B} in (3),(4),(5) and (6), respectively, and replacing k therein by γ ,

$$\mathbf{I}_1 = \left(\frac{1 - \gamma}{1 + \gamma} x_A, 0 \right), \quad (8)$$

$$\mathbf{E}_1 = \left(\frac{1 + \gamma}{1 - \gamma} x_A, 0 \right), \quad (9)$$

$$\mathbf{O}_1 = \left(\frac{1 + \gamma^2}{1 - \gamma^2} x_A, 0 \right), \quad (10)$$

The *TA* Apollonius circle

For the *TA* Apollonius circle, the two fixed points are the initial position of the Target $\mathbf{T} = (x_T, y_T)$ and the initial position of the Attacker $\mathbf{A} = (x_A, 0)$. Again, k is replaced by:

$$\alpha = \frac{V_T}{V_A}. \quad (12)$$

Now, we substitute the values of \mathbf{T} and \mathbf{A} above for \mathbf{A} and \mathbf{B} in (3),(4),(5) and (6), respectively, and replace k therein by α

$$\mathbf{l}_2 = \frac{1}{1+\alpha}(\mathbf{T} + \alpha\mathbf{A}) = \frac{1}{1+\alpha}(x_T + \alpha x_A, y_T), \quad (13)$$

$$\mathbf{E}_2 = \frac{1}{\alpha-1}(-\mathbf{T} + \alpha\mathbf{A}) = \frac{1}{1-\alpha}(x_T - \alpha x_A, y_T), \quad (14)$$

$$\mathbf{O}_2 = \frac{1}{1-\alpha^2}(\mathbf{T} - \alpha^2\mathbf{A}) = \frac{1}{1-\alpha^2}(x_T - \alpha^2 x_A, y_T), \quad (15)$$

Target survival and Critical Speed Ratio

Target survival is guaranteed if there is an overlapping of the region reachable by the Target before the Attacker (the interior of the TA Apollonius circle) and the region R_r reachable by the Defender before the Attacker, since within this overlapping, the Defender can perform its intended role of intercepting the Attacker before the Attacker captures the Target. Target survival is critical when the aforementioned overlapping diminishes into a single point at which the aforementioned two regions barely touch, or are tangent to one another.

An implicit assumption throughout the forthcoming analysis is that $\mathbf{T} = (x_T, y_T)$ is outside R_r .

$\bar{\alpha}$ is obtained when the TA Apollonius circle is tangent to the boundary of the shaded region R_r

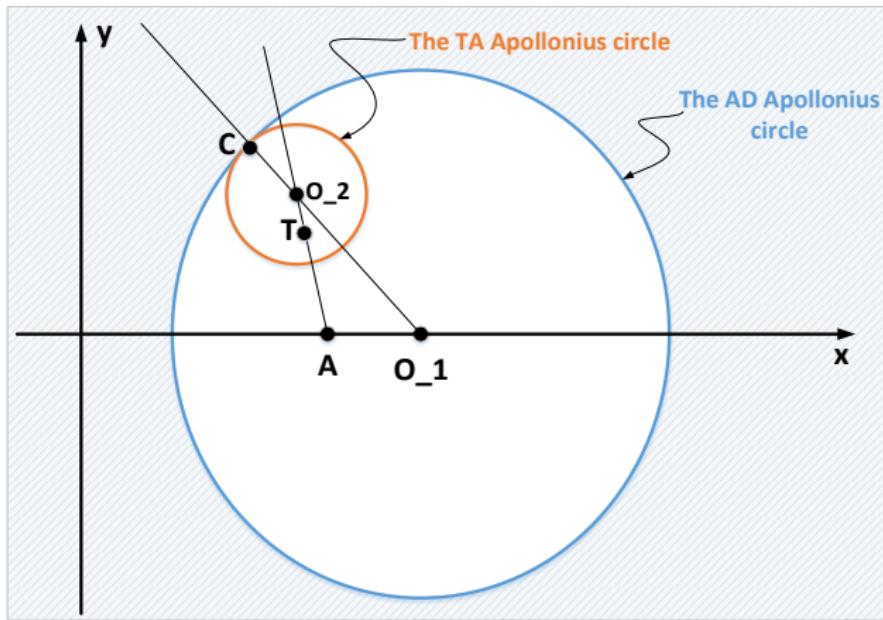

Figure: $\gamma < 1$

The critical speed ratio $\bar{\alpha}$, occurs when the *TA* Apollonius circle is *internally tangent* to the *AD* Apollonius circle, i.e., when the centers O_2 and O_1 of these two circles and their tangency point C are collinear. This happens when

$$r_1 - r_2 = |O_1 - O_2|. \quad (17)$$

Substituting for r_1, r_2, O_1 and O_2 from (11), (16), (11) and (15) respectively, and noting that $\gamma < 1$, one obtains

$$\begin{aligned} \frac{2\gamma}{1-\gamma^2}x_A - \frac{\alpha}{1-\alpha^2}d &= \left| \left(\frac{1+\gamma^2}{1-\gamma^2}x_A, 0 \right) - \frac{1}{1-\alpha^2}(x_T - \alpha^2x_A, y_T) \right| \\ &= \left[\left(\frac{1+\gamma^2}{1-\gamma^2}x_A - \frac{1}{1-\alpha^2}(x_T - \alpha^2x_A) \right)^2 + \frac{1}{(1-\alpha^2)^2}y_T^2 \right]^{1/2}. \end{aligned} \quad (18)$$

after several steps of simplification

$$\alpha^2 + \frac{d}{\gamma x_A} \alpha + \left[\left(\frac{1 - \gamma^2}{4\gamma^2} \right) \left(\frac{d}{x_A} \right)^2 - \frac{x_T}{x_A} \right] = 0 \quad (19)$$

Equation (19) is an improvement of equation (36) in [2]. while (19) is a quadratic equation in α , equation (36) in [2] is a quartic in α that has the same two roots of (19) in addition to the two irrelevant roots $\alpha \mp 1$. As a bonus, equation (19) is written in a self-verifying dimensionless form.

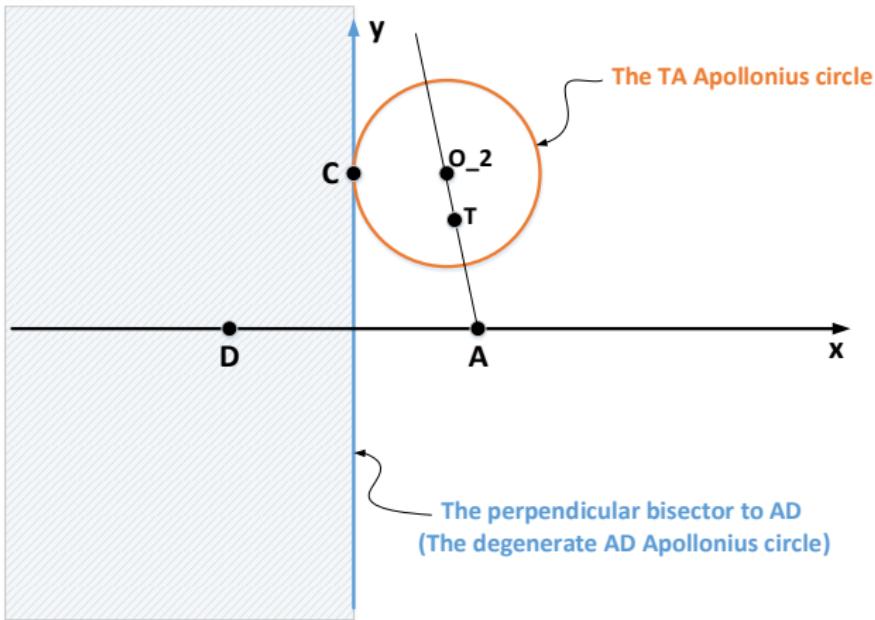

Figure: $\gamma = 1$

The critical speed ratio $\bar{\alpha}$ occurs when the *TA* Apollonius circle touches the *L.H.S.* of the *XY*-plane (Fig. 19), i.e., when

$$r_2 = \text{Absicessa of } O_2. \quad (20)$$

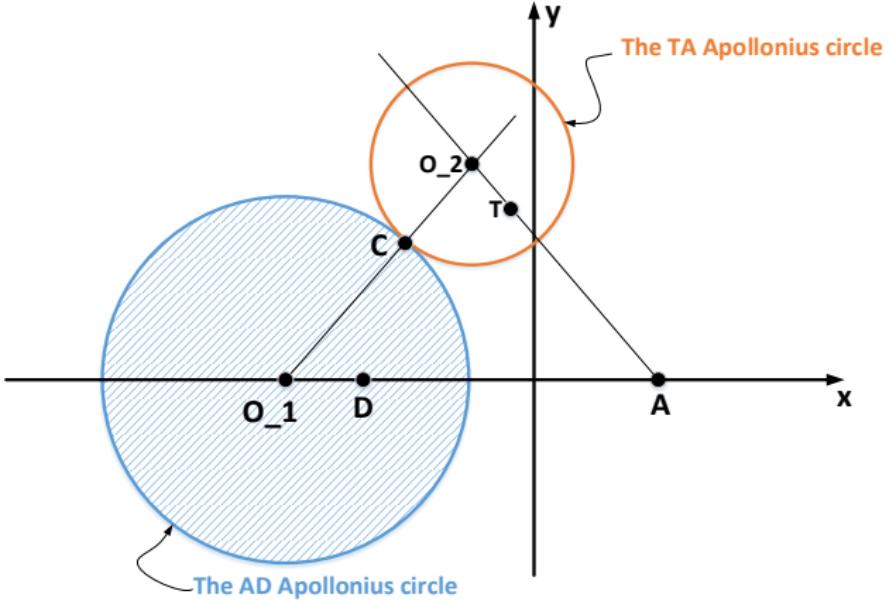

i.e., thanks to (15) and (16) when:

$$\frac{\alpha d}{1 - \alpha^2} = \frac{x_T - \alpha^2 x_A}{1 - \alpha^2}. \quad (21)$$

Multiplying (21) by $(1 - \alpha^2)$ (thanks to the fact that $\alpha \neq 1$), and rearranging, one obtains the following quadratic equation in α

$$x_A \alpha^2 + d\alpha - x_T = 0, \quad (22)$$

which is equation (12) in [3]. It is interesting to note that equation (21) is the special case ($\gamma = 1$) of (19), though (19) was derived under the assumption $\gamma \neq 1$.

Figure: $\gamma > 1$

The critical speed ratio $\bar{\alpha}$ occurs when the *TA* Apollonius circle is *externally tangent* to the *AD* Apollonius circle, i.e., when the centre O_2 , the tangency point C and the centre O_1 are collinear (Fig. 20), i.e., when

$$r_1 + r_2 = |O_1 - O_2| \quad (23)$$

Since $\gamma > 1$, we write

$$r_1 + r_2 = \frac{2\gamma}{|1 - \gamma^2|} + \frac{\alpha}{1 - \alpha^2} d = \frac{-2\gamma}{1 - \gamma^2} + \frac{\alpha}{1 - \alpha^2} d. \quad (24)$$

The above expression for $(r_1 + r_2)$ is exactly the negative of $(r_1 - r_2)$ in (18).

Equation (19) is thereby shown to hold for a slow Defender besides being true for a fast one. Therefore, we will use the quadratic formula (19) for all values of γ , and will solve it to obtain $\bar{\alpha}$ for any γ as

$$\begin{aligned}
 \bar{\alpha} &= \frac{1}{2} \left[-\frac{d}{\gamma x_A} \pm \left[\left(\frac{d}{\gamma x_A} \right)^2 - 4 \left(\frac{1-\gamma^2}{4\gamma^2} \right) \left(\frac{d}{x_A} \right)^2 + \frac{4x_T}{x_A} \right]^{1/2} \right] \\
 &= \frac{1}{2\gamma x_A} [-d \mp \gamma \sqrt{d^2 + 4x_T x_A}] \\
 &= \frac{1}{2\gamma x_A} [-\sqrt{(x_A - x_T)^2 + y^2} + \gamma \sqrt{(x_A + x_T)^2 + y_T^2}]
 \end{aligned} \tag{25}$$

Equation (25) was derived in [3] for $\gamma < 1$ and in [1] for $\gamma = 1$, provided $x_T > 0$. It is shown herein to hold for all values in γ , including $\gamma > 1$. Note that $\bar{\alpha}$ is definitely nonnegative and hence the minus sign in the solution for $\bar{\alpha}$ is rejected.

Pursuit-Evasion Voronoi Diagram

We develop a novel analytic expression for the pursuit-evasion Voronoi diagram that marks or borders the "safe" or "escape" region R_e for the Target, i.e., the region defined by the set of all coordinate points (x, y) such that if the target's initial position (x_T, y_T) is inside this region, then the target is guaranteed to survive (to escape the Attacker) provided both the Target and Defender implement their optimal strategies, and regardless of the policy adopted by the Attacker, whether optimal or not.

we obtain the general Voronoi diagram by rewriting the critically equation (19) as a relation between y_T and x_T , we write

$$(4\gamma\alpha x_A)d = -(1 - \gamma^2)d^2 + 4\gamma^2 x_A x_T - 4\gamma^2 \alpha^2 x_A^2 \quad (26)$$

finally we get,

$$\begin{aligned}
 p(x_T, y_T) = & 16\gamma^2\alpha^2x_A^4 \\
 & + 16\gamma^2\alpha^2x_A^2x_T^2 \\
 & - 32\gamma^2\alpha^2x_A^3x_T \\
 & + 16\gamma^2\alpha^2x_A^2y_T^2 \\
 & - (1 - \gamma^2)^2[x_A^4 + x_T^4 + y_T^4 + 2x_A^2x_T^2 + 2x_A^2y_T^2 + 2x_T^2y_T^2] \\
 & - (1 + \gamma^2)^2 * 4x_A^2x_T^2 \\
 & - 16\gamma^4\alpha^4x_A^4 \\
 & + 2(1 - \gamma^4)(2x_A^3x_T + 2x_Ax_T^3 + 2x_Ax_Ty_T^2) \\
 & - 8\gamma^2(1 - \gamma^2)\alpha^2(x_A^4 + x_A^2x_T^2 + x_A^2y_T^2) \\
 & + 16\gamma^2(1 + \gamma^2)\alpha^2x_A^3x_T
 \end{aligned} \tag{27}$$

Though (27) is a quartic equation, the actual Voronoi diagram is expected to be a quadratic curve and not a quartic curve. Note that we performed a squaring operation in obtaining (27), which doubled the pertinent degree from two to four. Hence, the Voronoi diagram is just a second-degree factor, part or branch of the fourth-degree curve depicted by (27). We will be able to identify the correct Voronoi diagram by rejecting any part of the curve that lies in R_r , i.e., the correct Voronoi diagram should define the border of R_e such that $R_e \supseteq R_r$.

Note that (27) is the general equation for the Voronoi diagram in our current *TAD* problem and it appears here for the first time.

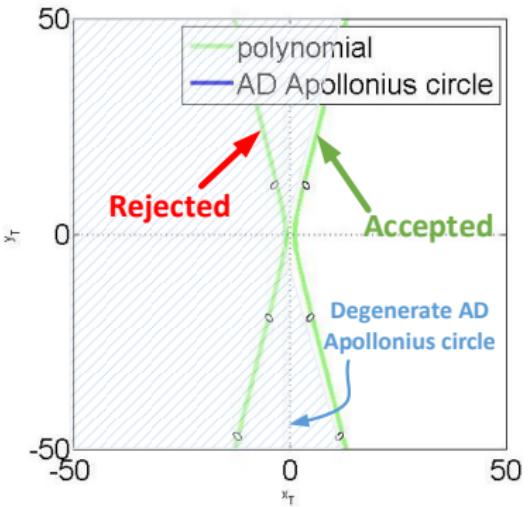

Figure: Generated computer output for the Voronoi diagram bordering the safe region for $x_A = 4$, $\alpha = 0.25$, $\gamma = 1$ (the safe region is the shaded area)

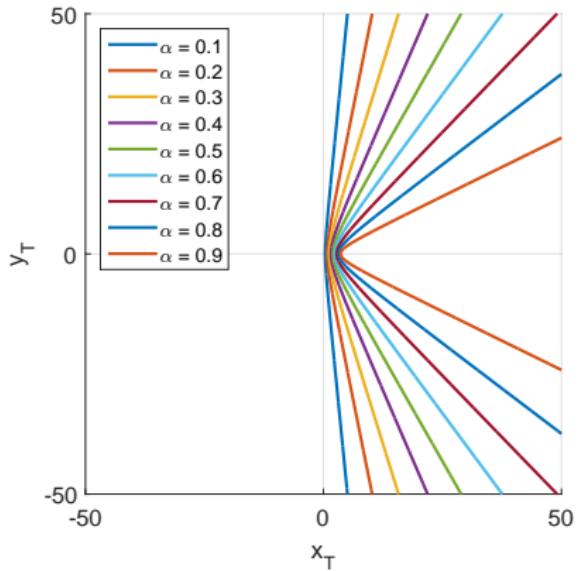

Figure: Various accepted branches of the voronoi diagram for $\gamma = 1$ and α as a parameter ranging from 0 to 1.

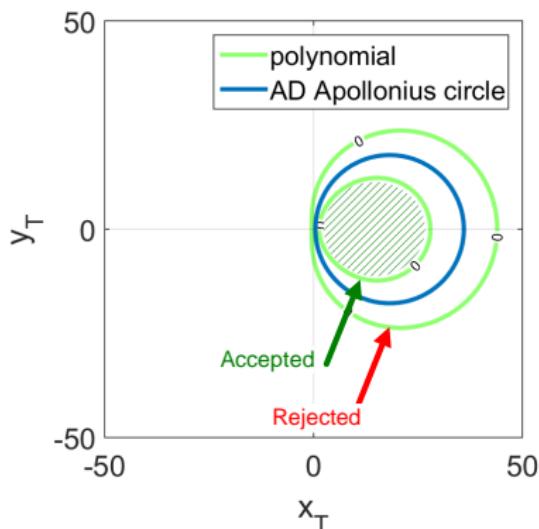

Figure: generated computer output for the Voronoi diagram bordering the safe region for $x_A = 4$, $\alpha = 0.25$, $\gamma = 0.8$ (the safe region is the unshaded area) the quartic in (27) produces two closed curves: one outside the AD-Apollonius circle (rejected) and the other inside the circle (accepted as the Voronoi diagram)

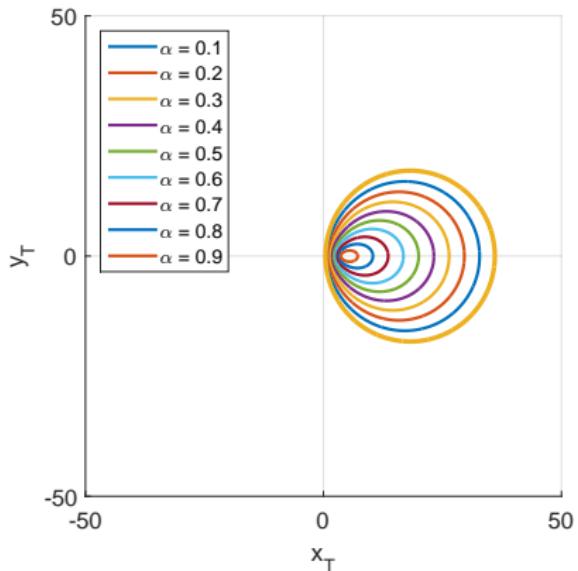

Figure: Various accepted branches of the voronoi diagram for $\gamma = 0.8$ and α as a parameter ranging from 0 to 1. These curves are computer generated from (27)

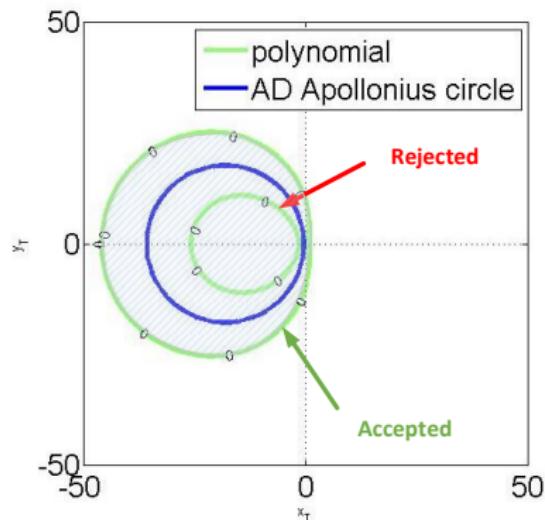

Figure: generated computer output for the Voronoi diagram bordering the safe region for $x_A = 4$, $\alpha = 0.25$, $\gamma = 1.25$ (the safe region is the shaded area) the quartic in (27) produces two closed curves: one inside the AD-Apollonius circle (rejected) and the other outside the circle (accepted as the Voronoi diagram)

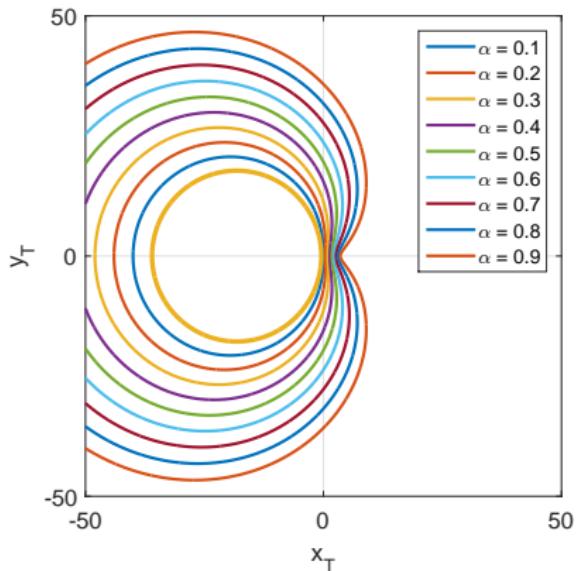

Figure: Various accepted branches of the voronoi diagram for $\gamma = 1.25$ and α as a parameter ranging from 0 to 1. These curves are computer generated from (27)

Optimal Strategies

Optimal Heading Angels

$$V_{T1} = -V_T \cos(\beta)$$

$$V_{T2} = V_T \sin(\beta)$$

$$R_{TM1} = RT1 - R_{M1}$$

$$R_{TM2} = RT2 - R_{M2}$$

$$R_{TM} = \sqrt{R_{TM1}^2 + R_{TM2}^2}$$

$$\lambda = \tan^{-1}\left(\frac{R_{TM2}}{R_{TM1}}\right)$$

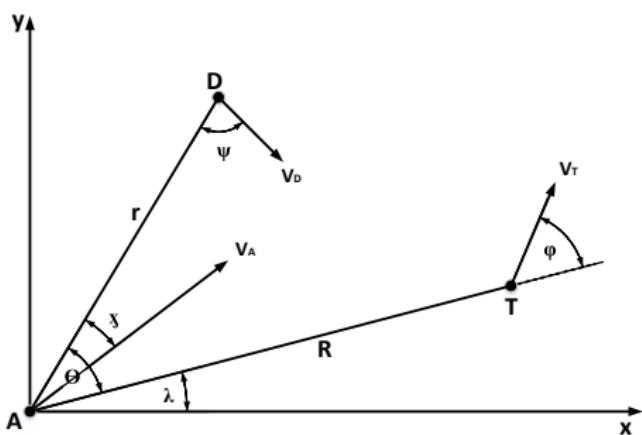

$$L = \sin^{-1}\left(\frac{V_T \sin(\beta + \lambda)}{V_M}\right)$$

$$V_{M1} = V_M \cos(\theta + HE)$$

$$V_{M2} = V_M \sin(\theta + HE)$$

$$V_{TM1} = V_{T1} - V_{M1}$$

$$V_{TM2} = V_{T2} - V_{M2}$$
